**Abstract.** Early stage technology startups rely critically on talented scientists and engineers to commercialize new technologies. And yet these startups compete with established technology firms to hire the best workers. Theories of ability sorting predict that high-ability workers will choose jobs in established firms that offer greater complementary assets and higher pay, leaving low-ability workers to take lower paying and riskier jobs in startups. We propose an alternative view in which heterogeneity in both worker ability and preferences enable startups to hire talented workers who have a taste for a startup work environment even at lower pay. Using a longitudinal survey that follows 2,394 science and engineering PhDs from graduate school into their first industrial employment, we overcome common empirical challenges by observing ability and stated preferences prior to entry into the labor market. We find that both ability and career preferences strongly predict startup employment with high-ability workers who prefer startup employment being the most likely to work in a startup. We show that this partly reflects dual selection effects whereby worker preferences result in a large pool of startup job applicants and startups make job offers to the most talented workers. Additional analyses confirm that startup employees earn approximately 17% lower pay. This gap is greatest for high-ability workers and persists over workers' early careers, suggesting that they accept a negative compensating differential in exchange for the nonpecuniary benefits of startup employment. Data on job attributes and stated reasons for job choice further support this interpretation.

**History:** Accepted by Toby Stuart, entrepreneurship and innovation.

**Funding:** This work was supported by the National Science Foundation SciSIP Award [Grant 1262270] and the Ewing Marion Kauffman Foundation (Junior Faculty Fellowship).

**Keywords:** startup employees • technology entrepreneurship • human capital • careers • joiners • scientists and engineers • compensating differentials

Talented people don't need to work for you; they have plenty of options. You should ask yourself a more pointed question: Why would someone join your company as its 20th engineer when she could work at Google for more money and more prestige? (Thiel 2014, p. 20)

## 1. Introduction

Technology startups play a key role in innovation, economic development, and job creation. Whereas prior entrepreneurship research focuses on understanding startup founders, less attention has been paid to those who join founders as early employees (Ouimet and Zarutskie 2014, Roach and Sauermann 2015, Sorenson et al. 2021). Early stage technology startups rely critically on talented scientists and engineers to commercialize new

technologies (Baron et al. 1996, Hsu 2007), and yet these startups may be disadvantaged relative to established firms in the labor market. Not only do established firms offer higher pay, greater job security, and other benefits such as on-the-job training (Oi and Idson 1999, Sørensen 2007, Bidwell and Briscoe 2010, Ouimet and Zarutskie 2014, Dahl and Klepper 2015, Burton et al. 2018), they also offer greater complementary assets, such as research tools, materials, and other talented workers that increase research and development (R&D) employees' productivity (Arora and Gambardella 1994, Agarwal and Ohyama 2013, Dahl and Klepper 2015). As such, early stage startups may struggle to hire high-ability workers, possibly constraining startups' growth and success (Beckman and Burton 2008, Agarwal et al. 2016, Honoré and Ganco 2023).

The existing empirical evidence on startup human capital provides an unclear picture. On the one hand, research shows that employees in small and young firms are paid less than their established firm counterparts, which is often interpreted as evidence of lower ability human capital (Brown and Medoff 1989, 2003; Oi and Idson 1999; Haltiwanger et al. 2013; Ouimet and Zarutskie 2014; Burton et al. 2018; Babina et al. 2019; Sorenson et al. 2021). On the other hand, high-growth VC-backed ventures are shown to hire talented workers by offering attractive workplace benefits, higher wages, and startup equity (Bengtsson and Hand 2013, Kim 2018). However, well-funded, high-growth ventures differ markedly from early stage startups that typically face severe resource constraints and greater uncertainty in their potential success. Thus, it remains an open question whether and why talented scientists and engineers would join startups as early employees when they have seemingly better options in established firms.

We argue that a deeper understanding of startup human capital requires attention to not only ability and wages, but also to differences in workers' preferences for employment in different types of firms. Indeed, recent evidence suggests that a meaningful share of individuals have a distinct taste for joining startups as non-founding employees in part because of the unique job attributes that startups offer relative to established firms (Roach and Sauermann 2015). Such heterogeneity in preferences may enable startups to attract high-ability employees with a taste for working in a startup even at lower pay (Stern 2004). Perhaps more importantly, we also consider the roles of ability and preferences together, which suggests that high-ability startup types face a particularly strong trade-off between the productivity benefits of working in an established firm and the preference benefits of working in a startup. If high-ability startup types perceive the nonpecuniary benefits of startup employment to exceed the opportunity costs of forgoing greater productivity benefits in established firms, then startups may be able to hire high-ability workers despite offering lower pay. Such a taste-based compensating differential also implies that interpreting wages as a proxy for ability will systematically underestimate startups' human capital.

The empirical challenge with studying workers' transitions into startup employment is that the determinants of employment outcomes are often unobservable to researchers. In addition, given that individuals' ability and preferences may be influenced over time and in different ways by their employment setting, observing workers' transition from one job to another complicates researchers' efforts to tease apart selection and treatment effects (Sørensen 2007, Elfenbein et al. 2010, Azoulay et al. 2017). We overcome these challenges through a longitudinal survey that follows a cohort of 2,394 science and engineering PhDs who were first surveyed as graduate students in U.S. research universities and then

again in their first time employment in industrial R&D. We supplement the survey with LinkedIn data to obtain comprehensive career profiles on all PhD survey respondents. A key advantage of our survey research design is that it provides direct measures of workers' typically unobserved career preferences along with a detailed proxy for ability. Moreover, by observing individuals several years prior to their first employment, we can examine selection prior to workplace treatment. We further disentangle the roles of ability and preferences using survey data on startup job applications and job offers, starting earnings, job characteristics, and reasons for choosing the first job.

We find that higher ability employees are more likely to work in early stage startups even though they earn significantly less than their observationally equivalent counterparts in established firms. Moreover, we observe strong self-selection into startups based on *ex ante* career preferences. Considering ability and preferences jointly yields a more complete picture: despite facing a greater trade-off between productivity and preference benefits, high-ability startup types are the most likely to work in a startup. This suggests that the preference benefits of startup employment outweigh the opportunity costs of forgoing greater productivity and higher pay in established firms. Supporting this interpretation, we show that startup employees earn approximately 17% less starting pay than their established firm peers, and this gap persists over their early careers. These patterns indicate that the lower earnings of startup employees reflect in part a taste-based compensating differential rather than lower ability. Finally, we show that ability and preferences play different roles at different stages of the job search process: workers apply to startups based on their career preferences, and startups make job offers to workers based on ability. Together these results suggest that preference-based self-selection creates a sizeable pool of startup job applicants, which, in turn, allows startups to select the most talented workers as early employees.

Our study contributes to several streams of the entrepreneurship literature. First, we contribute to a growing body of research seeking to understand startup human capital (Haltiwanger et al. 2013, Ouimet and Zarutskie 2014, Agarwal et al. 2016, Burton et al. 2018, Kim 2018, Babina et al. 2019, Sorenson et al. 2021). This work largely examines the relationship between firm size or age and employee wages, often interpreting lower wages as evidence of lower human capital. We advance this work by observing ability and preferences separately prior to first time employment, allowing us to tease apart ability and preference effects and consider their joint role in shaping startups' access to human capital. Our results suggest that lower wages in startup employment reflect a compensating differential rather than lower human capital. Finally, prior work compares firms across levels of size or age (Brown and Medoff

1989, Haltiwanger et al. 2013, Ouimet and Zarutskie 2014, Babina et al. 2019, Sorenson et al. 2021) or growth-stage, venture capital (VC)-backed ventures versus established firms (Bengtsson and Hand 2013, Kim 2018). We argue that early stage technology startups have unique characteristics—and face unique challenges—that deserve study in their own right (Hsu 2007).

Second, a large body of entrepreneurship research studies how ability or preferences explain entry into entrepreneurship as a founder. For example, studies suggest that high-ability individuals are more likely to transition to entrepreneurship in part because they can generate higher financial returns to their ability through residual claimancy (Jovanovic 1979, Elfenbein et al. 2010, Åstebro et al. 2011, Braguinsky et al. 2012, Hegde and Tumlinson 2021). Other studies show that individuals with preferences for autonomy, risk, and task variety realize nonpecuniary benefits from founding that may offset lower earnings than in wage employment (Kihlstrom and Laffont 1979, Evans and Leighton 1989, Hamilton 2000, Lazear 2005, Elfenbein et al. 2010, Åstebro et al. 2011). We extend this work to an under-studied entrepreneurial actor: startup early employees who join founders in their entrepreneurial efforts. In doing so, we demonstrate how studying ability and preferences jointly can yield novel insights, suggesting opportunities for future research to consider both aspects when studying decisions to become a founder and employment choice more broadly.

Third, entrepreneurship scholars have long studied whether and how organizational characteristics shape employees' subsequent founding decisions (Burton et al. 2002, Stuart and Ding 2006, Sørensen 2007, Elfenbein et al. 2010). A related emerging stream of research takes a careers perspective on entrepreneurship (Burton et al. 2016), showing that early employment experiences in different types of firms can have long-lasting implications for future entrepreneurship (Burton et al. 2002, Hsu et al. 2007, Elfenbein et al. 2010). We complement this work by studying how workers sort into different types of organizations to begin with, focusing on recent graduates who still have long careers ahead of them. We find significant selection with respect to ability and preferences, including founder types who sort into startups to acquire skills that can facilitate future founding (Gompers et al. 2005, Sørensen 2007, Elfenbein et al. 2010). As such, our results suggest the importance of accounting for employee selection when studying organizational treatment effects. More importantly, rather than studying selection and treatment in isolation, there may be value in considering them jointly. For example, it is likely that employees with different levels of preexisting entrepreneurial interests respond differently to contextual effects such as social influence, the arrival of entrepreneurial opportunities, or coworkers' offers to join a new venture (Roach and Sauermann 2015, Shah et al. 2019).

Finally, our results contribute to the more general literature on employee sorting and labor market matching. Although much of this literature focuses on the sorting of high-ability workers into high-quality firms (Becker 1973, Eeckhout 2018), recent work shows that high-ability workers may also sort into low-quality firms in exchange for higher pay (Bhaskarabhatla et al. 2021). We provide evidence on an alternative mechanism by which high-ability workers take jobs in resource-constrained firms at lower pay in exchange for the nonpecuniary benefits unique to those firms (see Stern 2004, Sorkin 2018). Our results suggest promising avenues for future research to incorporate heterogeneity in workers' preferences into theories of labor market matching.

## 2. Conceptual Framework

We begin by outlining differences in job characteristics between startups and established firms as well as differences in the types of workers these firms seek to hire (Section 2.1). Next, we draw upon ability-based theories to explain the prevailing view that high-ability workers choose jobs in established firms where they expect to be more productive and earn higher pay, leaving low-ability workers to take jobs in startups (Section 2.2). We then incorporate preference-based theories to argue that workers may choose to work in early stage startups because of their preferences for nonpecuniary job attributes even at lower pay (Section 2.3). Considering heterogeneity in both ability and preferences implies that high-ability workers with a taste for startup employment face a trade-off between the preference benefits from working in their desired work environment and the opportunity costs of forgoing greater productivity and higher wages in established firms. On the other hand, ability and preferences are reinforcing for high-ability workers with a preference for working in an established firm (Section 2.4). We also consider the role of labor demand, concluding that startups' opportunities to hire talented workers depend on the strength of the preference–productivity trade-off for high-ability startup types (Section 2.5).

Although selection into startups is of interest at all career stages, we focus on employees entering their first industry job. This provides advantages in terms of both conceptual development and empirical analysis. In particular, focusing on first time employment allows us to abstract away from potential confounding effects of prior work experience and organizational influences (Burton et al. 2002, Elfenbein et al. 2010). Similarly, studies of job choice later in the career face the challenge that mobility is often endogenous because those who leave their employers may be selected on unobserved characteristics. This selection problem is less relevant for recent graduates, all of whom must make a first time employment decision after graduation.

## 2.1. Employment in Early Stage Technology Startups

We conceptualize early stage technology startups as small, young firms founded to commercialize emerging technologies. As such, our focus is on new firms rather than the more mature VC-backed ventures often considered in prior work.<sup>1</sup> In the following, we highlight three aspects of startups and established firms that are particularly relevant for our discussion of job choice and employment outcomes: the nature of the work and the resulting demand for talented workers, the availability of resources, and differences in specific job attributes. By focusing on key differences between early stage startups and established firms, we abstract away from heterogeneity among different startups or different established firms. In addition, we assume that established firm employment is the conventional career path for most recent graduates, whereas working in a startup is the less common alternative (National Science Board 2014).

First, the primary activity of early stage technology startups is the commercialization of new technologies that are often at the cutting edge of their field. Consider, for example, the growing number of startups in areas such as artificial intelligence (AI), biotechnology, alternative energy, and robotics. Given their focus on technology commercialization, such startups require talented scientists and engineers as early employees to increase their chances of technological success (Andersson et al. 2009). In contrast, established technology firms have portfolios of R&D projects that include both cutting-edge projects to commercialize new technologies as well as incremental projects to sustain existing technologies (Cohen and Klepper 1996). For example, firms such as Amazon, Google, and Microsoft have projects at the frontiers of AI and robotics as well as projects to make incremental improvements to technologies in existing lines of business. This has important implications for the types of employees that startups and established firms seek to hire: whereas startups need primarily high-ability scientists and engineers, large established firms employ both higher ability employees to work on cutting-edge projects and lower ability employees to work on incremental projects.

Second, early stage startups face severe resource constraints relative to established firms (Evans and Leighton 1989, Hsu 2007, Agarwal and Ohyama 2013). These constraints make it difficult for them to invest in the complementary assets that employees need to successfully commercialize new technologies, such as advanced research laboratory infrastructure or computational equipment. Resource constraints also make it difficult to offer competitive salaries (Hsu 2007) and attract complementary human capital that high-ability employees often need to increase their productivity (Bhaskarabhatla et al. 2021).

Finally, early stage startups differ from established firms with respect to various job attributes associated

with their small size and young age. For example, startups tend to have flat hierarchies and low levels of bureaucracy, providing employees with considerable autonomy and task variety (Lazear 2005, Sørensen 2007, Elfenbein et al. 2010). Startups may also offer aspiring founders opportunities to develop skills and experience that are beneficial to future transitions to entrepreneurship (Gompers et al. 2005, Sørensen 2007, Elfenbein et al. 2010). Moreover, as startups grow and achieve success, they may offer early employees opportunities for rapid career advancement (Neff 2012, Sorenson et al. 2021). Large, established firms, on the other hand, tend to have greater bureaucracy and routinized organizational practices (Sørensen 2007) with formalized career ladders within specialized functional roles (Baron et al. 1996, Sørensen 2007, Cappelli 2008, Bidwell and Briscoe 2010). At the same time, established firms offer benefits typically unavailable in startups, such as on-the-job training and other skill-development programs that can be particularly attractive to early career workers (Bidwell and Briscoe 2010). Finally, established firms offer greater job security, whereas startup employees face greater career risk due to their employers' higher likelihood of failure (Hsu 2007, Neff 2012, Sorenson et al. 2021).<sup>2</sup>

Building on this discussion of differences between jobs in early stage technology startups and established technology firms, we next consider the potential role of ability and preferences in shaping individuals' decision to work in a startup.

## 2.2. Ability and Startup Job Choice

A prominent stream of research in economics and strategy considers how employees of varying ability sort into firms of varying quality (Becker 1973, Agarwal and Ohyama 2013, Eeckhout 2018). A central insight of this research is that income-maximizing, high-ability workers choose jobs in firms that have greater resources to invest in complementary assets that increase their productivity and offer them higher pay through rent sharing.<sup>3</sup> In the context of R&D, such complementary assets include physical R&D infrastructure, research tools, and other talented workers. Given that early stage startups typically lack the financial resources to invest in such complementary assets and offer higher pay, high-ability workers instead are more attracted to jobs in established firms.

Although the literature focuses on complementary assets in the form of physical and human capital, complementarities may also arise between workers' ability and the nature of their work. As discussed, cutting-edge R&D projects are more challenging and more likely to be successful if performed by high-ability workers (Andersson et al. 2009). Similarly, high-ability scientists and engineers may expect to be more productive working on cutting-edge R&D projects rather than incremental projects. Given that early stage technology startups

are typically founded to commercialize discoveries at the frontier of science and technology (Gans and Stern 2003, Hsu 2007), high-ability workers may find startup employment particularly attractive. At the same time, established firms also offer opportunities to work on cutting-edge R&D projects in addition to offering greater complementary assets and higher pay. As such, high-ability workers should still find jobs in established firms more attractive than in startups.

Recent research, however, suggests that high-ability workers do not always work in higher quality firms. In particular, Bhaskarabhatla et al. (2021) find that high-ability inventors move to firms with lower innovative capabilities in exchange for higher pay. Applied to our context, this suggests that high-ability workers might choose jobs in early stage startups with lower complementarities if offered higher pay than they could earn in established firms. Although there is evidence that later stage, VC-backed firms can attract high-ability workers by paying higher wages (Kim 2018), resource-constrained, early stage startups are likely unable to offer such a wage premium.

Of course, resource-constrained startups may offer employees equity instead of higher pay (Hand 2008). Indeed, the entrepreneurship literature emphasizes expectations of future financial payoffs through founder equity in explaining the transition of high-ability individuals from wage employment to entrepreneurship (Åstebro et al. 2011, Braguinsky et al. 2012, Hegde and Tumlinson 2021). Given the large disparity between founder and employee equity shares, however, startup employees can expect much smaller financial payoffs if the venture is successful. Moreover, given the low probability of a successful exit, the realized value of employee startup equity in most instances is zero.<sup>4</sup> Consistent with this, Aran and Murciano-Goroff (2021) show through a recent survey of U.S. workers with science, technology, engineering, and mathematics degrees that only 10% viewed startup equity as primarily financial compensation. Instead, 30% viewed it as equivalent to a lottery ticket and 25% as an incentive alignment mechanism, drawing into question the role of equity as a key driver of the decision to work in a startup. Moreover, stock options are also offered by many publicly traded technology companies based on a known share price, making them more valuable to workers. Thus, whereas equity is likely necessary for most workers to accept a startup job, it may be insufficient to lure high-ability workers away from the higher pay and attractive stock options available in established firms.

Taken together, this discussion suggests that if high-ability workers primarily seek to maximize their productivity and income, they are unlikely to choose jobs in resource-constrained startups over jobs in established firms.

### 2.3. Career Preferences and Startup Job Choice

Going beyond the assumption of income maximization, a rich literature explores the role of individuals' preferences for nonpecuniary benefits in shaping career choice. This literature argues that some workers are willing to accept lower pay for jobs that offer desirable attributes such as freedom, intellectual challenge, or security (Rosen 1986). For example, Stern (2004) shows that R&D jobs that offer nonfinancial aspects that scientists value, such as autonomy and opportunities to publish, also pay lower salaries, concluding that "scientists pay to be scientists." Although this work often assumes homogeneous preferences, other studies highlight that individuals vary in the degree to which they value particular nonpecuniary benefits (Elfenbein et al. 2010, Roach and Sauermann 2010, Agarwal and Ohyama 2013). This heterogeneity, in turn, suggests that workers may choose jobs in different types of firms based in part on their individual preferences for specific job attributes.

Although we study startup employment and not founding, the entrepreneurship literature offers guidance on how preferences can be conceptualized. Much of the literature focuses on preferences for specific job attributes, such as autonomy (Evans and Leighton 1989), risk (Kihlstrom and Laffont 1979), or task variety (Lazear 2005, Åstebro et al. 2011). Other theories consider a taste for a specific employment setting (e.g., taste for entrepreneurship) that involves bundles of job attributes (Stern 2004, Elfenbein et al. 2010, Roach and Sauermann 2015). We build on Roach and Sauermann (2015), who link the two levels to understand individuals' career preferences for becoming a founder (founder types), joining a startup as an employee with no intention of becoming a founder (joiner types), or working in an established firm (established firm types).<sup>5</sup> We expand upon their ideas within the context of scientists and engineers choosing between R&D jobs in early stage technology startups versus established technology firms.

First, founder types are individuals who aspire to become an entrepreneur in the future. Founder types are characterized by preferences for job attributes that align with entrepreneurship, such as autonomy, risk, or performing a variety of tasks (Kihlstrom and Laffont 1979, Evans and Leighton 1989, Lazear 2005, Åstebro and Thompson 2011).<sup>6</sup> Because most aspiring founders lack an entrepreneurial opportunity at the beginning of their careers (Shane 2000), they first seek employment rather than found their own firm.<sup>7</sup> Working in a startup may also enable founder types to acquire additional skills and knowledge that better prepare them to start their own company in the future (Gompers et al. 2005, Sørensen 2007, Elfenbein et al. 2010).

Second, many individuals are attracted to joining a startup as an employee but have little interest in becoming a founder themselves (Roach and Sauermann 2015). Such joiner types share with founder types preferences

for job attributes typically offered in startups, such as autonomy and risk, but also differ in meaningful ways that make their career preference unique. For example, joiner types may be attracted to working in a small firm because it enables them to contribute directly to a venture's success, but they may not wish to bear the greater responsibility that comes with being a founder. Joiner types may also seek to work in a startup out of an interest in commercialization work activities, but they may have little interest in the managerial activities required of founders (Elfenbein et al. 2010). At the same time, they may appreciate opportunities to work on a broader range of commercialization activities than offered by established firms where R&D positions tend to be more specialized (Lazear 2005, Elfenbein et al. 2010). Finally, some scientists and engineers may find startups attractive because they can work on cutting-edge R&D projects that offer not only greater productivity (see earlier), but also intrinsic rewards, such as intellectual challenge (Stern 2004, Roach and Sauermann 2015, Bhaskarabhatla et al. 2021).

In contrast to founder and joiner types who are both attracted to working in a startup, others prefer to work in an established firm. These established firm types have career preferences that reflect, in part, a desire for job security (Kihlstrom and Laffont 1979, Halaby 2003), well-defined job roles and career ladders (Cappelli 2008, Bidwell and Briscoe 2010), and greater organizational structure and formalization (Halaby 2003). They may also value other benefits offered by established firms, such as on-the-job training (Bidwell and Briscoe 2010) and organizational prestige (Burton et al. 2002, Bidwell et al. 2015). With respect to work activities, some established firm types may be attracted to cutting-edge R&D projects in large innovative firms (e.g., Google DeepMind and Amazon Science), whereas others may prefer to work on more incremental R&D projects that are less demanding and more certain in their outcomes.

Although we make no assumptions about the long-term stability of individuals' career preferences, we contend that preferences expressed prior to entry into the labor market shape which jobs individuals apply to and which job offers they accept if given the choice.<sup>8</sup> More specifically, founder and joiner types are more likely than established firm types to choose jobs in startups, whereas the latter are more likely to choose jobs in established firms. Of course, even founder and joiner types will not accept any startup job regardless of the startup's potential quality; they may well turn down offers from low-quality startups to instead work in established firms.<sup>9</sup> This discussion leads us to now consider more explicitly how employment outcomes reflect the joint role of ability and preferences.

#### 2.4. Joint Effects of Ability and Preferences on Startup Job Choice

Whereas the literature largely studies ability and preferences separately or assumed homogeneous preferences,

we consider heterogeneity in both ability and preferences jointly. Doing so allows us to develop unique expectations regarding which individuals may choose to work in a startup versus an established firm. For simplicity, we consider four broad categories of workers, defined by different combinations of ability (high versus low) and career preferences (founder/joiner versus established firm types). Given that founder and joiner types share similar preferences for startup employment, we combine them into a single category of startup types to contrast them more clearly with established firm types (see Figure 1).

If, as argued, the productivity benefits are greater in established firms than in startups, whereas the preference benefits are greater in a worker's preferred firm type, then ability and preferences are reinforcing for high-ability established firm types who maximize both productivity and preference benefits when working in an established firm. Although low-ability established firm types do not expect the same level of productivity benefits from working in an established firm as their high-ability peers, ability and preferences are still reinforcing such that low-ability established firm types should choose jobs in established firms rather than in startups.

In contrast, ability and preferences are offsetting for startup types, who face a trade-off between the greater preference benefits of working in a startup and the opportunity costs of forgoing greater productivity and higher pay in an established firm. Assuming that the preference benefits of working in a startup are largely independent from ability, this trade-off is greatest for high-ability startup types who face higher opportunity costs from not working in resource-rich established firms. Although we do not have priors on the relative size of preference benefits versus opportunity costs, this trade-off suggests that high-ability startup types may be less likely to choose jobs in startups than low-ability startup types.

Considering ability and preferences jointly raises the question of whether they are correlated (see Jovanovic 1994). Our discussion in Section 2.2 suggests that, if established firms offer greater financial returns to ability, then high-ability individuals may prefer to work in an established firm. In that case, ability and established firm career preferences would be positively correlated and yield the same prediction, namely, that high-ability individuals will work in established firms. However, career preferences in our conceptualization reflect a much broader range of factors, including not only income but also nonpecuniary factors such as autonomy, risk, and intrinsic rewards from working on cutting-edge technologies, suggesting that ability and career preferences may not be correlated. Given that there is little theoretical rationale or prior evidence suggesting a strong relationship between ability and career preferences, we expect that some high-ability individuals prefer to work in an established firm, whereas others prefer to work in a startup. We show in Section 4.1 that there is indeed no

**Figure 1.** Predictions for Different Ability–Preference Combinations

	<b>Startup type:</b> Greater preference benefits from startup employment	<b>Established firm type:</b> Greater preference benefits from established firm employment
<b>High ability worker:</b> Greater productivity benefits from access to resources and complementary assets.  In greater demand for cutting-edge R&D projects in both startups and established firms	<b>High ability startup type</b> Stronger trade-off between opportunity costs (forgoing greater productivity benefits from working in established firm) and preference benefits from working in startup  Given startup demand for cutting-edge projects: <ul style="list-style-type: none"><li>▪ <i>If preference benefits are greater than opportunity costs, then most likely to work in a startup</i></li><li>▪ <i>If preference benefits are less than opportunity costs, then less likely to work in a startup than low ability startup types</i></li></ul>	<b>High ability established firm type</b> Stronger reinforcement between productivity benefits and preference benefits from working in established firm  Given established firm demand for cutting-edge projects: <ul style="list-style-type: none"><li>▪ <i>Least likely to work in a startup</i></li></ul>
<b>Low ability worker:</b> Lower productivity benefits from access to resources and complementary assets.  In greater demand for incremental R&D projects in established firms	<b>Low ability startup type</b> Weaker trade-off between opportunity costs and preference benefits from working in startup  If startups can hire high ability workers: <ul style="list-style-type: none"><li>▪ <i>Less likely to work in a startup than high ability startup types, but more likely than established firm types</i></li></ul> If startups cannot hire high ability workers: <ul style="list-style-type: none"><li>▪ <i>Most likely to work in a startup</i></li></ul>	<b>Low ability established firm type</b> Weaker reinforcement between productivity benefits and preference benefits from working in established firm  Given established firm demand for incremental projects: <ul style="list-style-type: none"><li>▪ <i>Less likely to work in a startup than startup types</i></li></ul>

systematic relationship between ability and career preferences in the data, supporting our conceptual and empirical approach to examining them as independent factors.

## 2.5. Demand for Startup Human Capital

Up to this point, we focus on workers' (supply-side) job choice. However, whether workers can choose their preferred job also depends on firms' demand for workers of differing ability. The implications for individuals with established firm preferences are quite clear: As argued in Section 2.1, established firms seek to hire both high- and low-ability workers for different types of R&D projects such that most individuals should have job options in established firms. Given that high-ability, established firm types expect higher productivity benefits as well as higher preference benefits from working in an established firm, they should be the least likely to work in a startup, followed by low-ability established firm types.

The implications of demand are more ambiguous for startup types. We argued that early stage technology startups seek to hire high-ability workers needed to commercialize cutting-edge technologies.<sup>10</sup> As such, high-ability startup types should be more likely than low-ability startup types to receive startup job offers and, thus, have the option to act on their preferences to

work in a startup. At the same time, they face greater opportunity costs by forgoing the productivity benefits of established firm employment. If they find the preference benefits of startup employment greater than the opportunity costs, then they should be more likely to accept a startup job offer. Moreover, if the number of startup jobs is small relative to the number of applicants, then startups can select the most talented workers, leaving low-ability startup types to take more readily available jobs in established firms. In that case, the share of high-ability workers would be higher in startups than in established firms. If, on the other hand, high-ability startup types consider the opportunity costs of working in a startup too high, then startups must settle for low-ability startup types who are more likely to accept job offers given their preferences and lower opportunity costs.

Figure 1 summarizes our conceptual framework and predictions for the four ability–preference combinations in terms of transitions into startup employment. Some of the predictions are unambiguous and testable. However, the actual shares of individuals in each cell as well as the trade-offs between preference benefits and opportunity costs—as reflected especially in the job choices of high-ability startup types—require empirical exploration.

### 3. Data and Measures

Studying the role of ability and preferences in employee job choice presents two key empirical challenges. First, ability and preferences are often unobserved. As such, many studies infer ability or preferences from observed wages and employment decisions (Brown and Medoff 1989, Ouimet and Zarutskie 2014, Sorenson et al. 2021) or account for them through fixed effects (Abowd et al. 1999, Stern 2004, Kim 2018, Sorkin 2018, Bhaskarabhatla et al. 2021). Whereas such approaches can be extremely useful, they typically do not allow researchers to investigate the separate roles of both ability and preferences on employment outcomes. Second, most data sources observe workers after they have made their first employment choice, making it difficult to distinguish selection into different types of firms from treatment effects of the employment context on ability or preferences (Sørensen 2007, Elfenbein et al. 2010). For example, when observing startup employees' preferences after joining a startup, it is difficult to discern whether these preferences determined individuals' decision to work in a startup or whether startup employment influenced their preferences.

We overcome these challenges through a longitudinal survey that includes direct measures of individuals' ability and stated preferences prior to entry into the job market.<sup>11</sup> This novel research design allows us to examine the separate roles of ability and preferences in explaining first time employment outcomes. We also draw upon subsequent survey responses on startup job applications and job offers, starting compensation, and ex post job attributes and reasons for job choice to examine underlying assumptions of our conceptual framework and explore alternative explanations. Although our data have their own limitations, they allow us to provide valuable insights on workers' sorting into different types of firms.

#### 3.1. Survey Strategy and Supplementary Data

Our survey follows a cohort of science and engineering PhDs from 39 top-tier U.S. research universities from graduate school to their first industry employment. We selected universities based primarily on PhD program size, also ensuring variation in private/public status and geographic region. The 39 universities in our sample produced roughly 40% of the graduating PhDs in science and engineering fields in 2009 (National Science Foundation 2009). Respondents were contacted through their university email address listed on department websites and invited to participate in an online survey that asked about their graduate school experience and career goals, using up to three reminders. Respondents were first surveyed in 2010 or 2013 when in graduate school (*PhD survey*, 10,781 respondents, 30% response rate adjusted for undelivered emails) and then again

after graduation in 2013 or 2016 after they had transitioned into full-time employment (*employment survey*, 73% adjusted response rate). Together, the PhD and employment surveys provide detailed microdata on individuals' stated preferences and characteristics up to three years prior to their first industry employment as well as information on their job search and first full-time job, including starting pay and employer characteristics.

To ensure comprehensive data on employment outcomes, we supplemented the employment survey with career profile data from LinkedIn and a Google search for all respondents to the PhD survey. We first searched for each respondent by name and PhD university and then verified a match by comparing the field of study and the specific years in the PhD program as reported in the PhD survey. These external career profile data provide employment outcomes for nonrespondents to the employment survey as well as more detailed data on job title and employer characteristics for all respondents. Combining survey and external data provides employment outcomes for 92% of PhD survey respondents.

Our sample consists of 2,394 PhDs who entered U.S. industry employment in R&D-related occupations between 2010 and 2016 and for whom we have complete data from the PhD survey. We restrict the sample to R&D-related occupations to focus on workers choosing between similar jobs in startups and established firms and because these are the most prevalent first industry occupations for science and engineering PhDs (82.5% of industry-employed respondents in our data).<sup>12</sup> R&D-related occupations are identified based on either survey-reported work activities (i.e., respondents who reported that they spend 40%–100% of their time on basic research, applied research, and/or development work activities) or the LinkedIn job title (e.g., research scientist, research engineer, data scientist, etc.). For PhDs for whom we have both survey-reported work activities and LinkedIn job titles, the correspondence for R&D occupations is 95.8%. Whereas studies employing administrative data such as the U.S. Census or Statistics Denmark typically rely upon indirect proxies of founder status, such as being among the first or highest paid employees (Sørensen 2007, Azoulay et al. 2020), we are able to directly identify founders and startup executives (e.g., chief technology officer) and exclude them from our sample of employees.<sup>13</sup>

Despite our focus on recent doctorates taking jobs in different types of firms, it is useful to understand whether and how PhDs who go into industry differ from those who remain in academia. Table A1 in the online appendix uses the survey data from all graduates to compare our sample of industry PhDs to PhDs who remained in academia either as a postdoc or in a tenure or nontenure track university position with respect to ability and preferences as measured in the PhD survey.<sup>14</sup> The results show no significant differences in ability. However, PhDs who transitioned to industry reported

stronger preferences for financial pay and commercialization activities as well as weaker preferences for autonomy and basic research activities (see also Roach and Sauermann 2010, Agarwal and Ohyama 2013). For our purposes, these results make two important points. First, PhDs entering industry are less “academic” than those who remain in academia, stating quite balanced preferences for both nonpecuniary factors such as autonomy as well as financial compensation (see summary statistics in Table 1). As such, the trade-offs between pecuniary and nonpecuniary job attributes discussed in Section 2.4 should be of high relevance for our sample. Second, despite individuals’ self-selection into industry, there remains significant heterogeneity within our sample with respect to both ability and preferences, allowing

us to investigate potential sorting into startups versus established firms.

### 3.2. Variables

**3.2.1. Employment in Early Stage Startups.** To identify whether an individual’s first industry job was in an early stage startup, we rely upon the employment survey and LinkedIn data in a two-step process. First, we asked respondents in the employment survey to state their first employer’s age (years since founding) and size (number of employees) at the time they started employment. For individuals who did not respond to the employment survey or for whom firm age and size were missing, we used LinkedIn data to ascertain employer age and size in the year they started their job.<sup>15</sup>

**Table 1.** Summary Statistics by Type of Employment and Ex Ante Career Preference ( $n = 2,394$ )

Sample share	Employer type		Ex ante career preference				
	Startup (11.6%)	Est. firm (88.4%)	Founder (4.1%)	Joiner (7.6%)	Indifferent (41.7%)	Est. firm (36.6%)	Other (10.0%)

Other field (row%)	0.10	0.90	0.05	0.09	0.36	0.36	0.14

Much of the prior research examining startup human capital focuses on either firm size or age separately, typically using continuous measures of these firm attributes (Brown and Medoff 2003, Gompers et al. 2005, Ouimet and Zarutskie 2014, Dahl and Klepper 2015). Our approach combines both size and age to distinguish early stage startups as qualitatively different from other types of employers (see also Burton et al. 2018, Sauermann 2018, Sorenson et al. 2021). We code individuals as working in an early stage startup if their employer was founded within five years and had 50 or fewer employees in the year they started employment. All other individuals were coded as working in an established firm, which includes large established firms (e.g., Google) and corporate spinoffs (e.g., Google Life Sciences spinoff Verily) as well as high-growth ventures that are both young and large (e.g., 23andMe, Uber, etc.). We examine the robustness of our results to alternative operationalizations of startup employment and to the stage of startup VC funding in Section 4.6.

In our sample, 11.6% of PhDs are employed in early stage startups. Among these, 45% are employed in startups with 10 or fewer employees, and the average startup age is 2.7 years, confirming that employers coded as early stage startups are indeed very small and young firms. The preponderance of PhDs work in R&D-intensive firms in high-tech industries. Among startup employees, 35% are in computer and information technology, 28% in biotechnology or other biomedical, 15% in R&D services, and 3% in energy. Among established firm employees, 42% are in computer and information technology, 17% in biotechnology or other biomedical, 10% in R&D services, and 3% in energy. Leading technology firms such as Amazon, Dow Chemical, Genentech, Google, Intel, Microsoft, Pfizer, and Qualcomm account for a large share of established firm employment in our sample.

**3.2.2. Ability.** Prior entrepreneurship research uses a variety of proxies for unobserved worker ability, including educational attainment, work experience, and prior wages (Hamilton 2000, Elfenbein et al. 2010, Åstebro et al. 2011, Agarwal and Ohyama 2013, Ouimet and Zarutskie 2014). Others either measure or control for ability through individual fixed effects (Abowd et al. 1999, Stern 2004, Kim 2018, Babina et al. 2019). Given that our sample consists of PhDs at the beginning of their careers, commonly used proxies either do not vary (e.g., level of education) or are unavailable (e.g., prior wages). Instead, we follow recent work by employing a fine-grained measure of ability that is particularly relevant when considering PhD employment outcomes and performance: the quality of PhD students' university department (Agarwal and Ohyama 2013, Roach and Sauermann 2015, Cohen et al. 2020).

Department rank is a useful proxy for PhD ability given that highly ranked departments are more selective in admitting PhD students and provide more rigorous scientific training. PhDs from higher ranked departments are also likely to have better employment prospects and expect to be more productive in their R&D activities than PhDs from lower ranked departments. Moreover, PhD department ranking is an observable signal to employers of a worker's potential ability and should be particularly important for novice scientists and engineers who lack industry work experience (Spence 1973, Agarwal and Ohyama 2013, Hegde and Tumlinson 2021). Finally, whereas wages may reflect ability as well as preferences (via preference-based compensating differentials; see Stern 2004), our ability measure is less likely to reflect preferences, making it better suited to examine the role of ability separate from preferences in shaping employment outcomes.<sup>16</sup>

To construct our ability measure, we matched respondents' university departments to the National Research Council's survey-based rankings of doctoral programs, which reflect aspects such as research funding, faculty publication productivity, and program research activity (National Research Council 2010).<sup>17</sup> To facilitate interpretation, we reverse-coded PhD department rank so that positive regression coefficients indicate a positive relationship between ability and the outcome variable. Given the skewed distribution of this measure, we use the natural log in regression analyses as well as categorical variables for ability quartiles.<sup>18</sup>

To examine the validity of PhD department rank as a proxy for ability, we regress starting earnings as reported in the employment survey onto PhD department rank, controlling for demographics, degree field, and year of employment. The intuition is that, if employers use department quality as a signal of PhDs' ability, then department rank should significantly predict starting pay above and beyond other observable characteristics. The results reported in Online Table A2 confirm this intuition, supporting our interpretation of PhD department rank as a meaningful proxy for ability.

In our sample, PhD department rank reflects 677 different university departments across a broad range of fields. As such, this measure is much more fine-grained and closer to the individual level than commonly used coarse ability measures, such as highest degree (e.g., high school, bachelor's, master's) or years of education (for notable examples, see Card 1996, Abowd et al. 1999, Hamilton 2000). At the same time, PhD department rank does not vary across individuals within a department. To examine the robustness of our results to this potential limitation, we constructed an alternative individual-level ability measure using a regression approach that incorporates information from signals of individual ability including publications, patents, research awards,

and starting pay (see Online Appendix B for details). Although this approach has its own limitations, it yields substantively identical results as using PhD department rank, strengthening confidence in our featured measure.

**3.2.3. Preferences.** As discussed in Section 2.3 (ex ante) preferences can be conceptualized with respect to careers in a startup or established firm as well as to specific job attributes, such as autonomy and risk. Although our focus is on the former, we also measure certain job attribute preferences that are particularly relevant for startup employment and that help us understand our career preference measures.

**3.2.3.1. Preferences for Specific Job Attributes.** We measure preferences for five job attributes featured in the entrepreneurship literature that may distinguish individuals drawn to employment in a startup or an established firm (see Section 2.3). First, we proxy for risk tolerance using a lottery-type question that asked respondents, “Imagine you have the choice between winning \$1,000 for sure or winning \$2,000 with a 50% chance. Please indicate which option you prefer.” Respondents answered using a 10-point scale that ranged from “strongly prefer 100% chance to win \$1,000” to “strongly prefer 50% chance to win \$2,000.” Higher values reflect a greater willingness to choose a riskier outcome with a higher potential payoff, which we interpret as a greater tolerance for risk. Second, we build on the Survey of Doctorate Recipients (National Science Foundation 2008) to measure respondents’ preferences for autonomy (“freedom to choose research projects”) and income (“financial income”) by asking them to rate the importance of these job attributes on a five-point scale ranging from “not at all important = 1” to “extremely important = 5.” Finally, we measure individuals’ preferences for managerial (“management/administration”) and commercialization work activities (“commercializing research results into products or services”) on a five-point scale ranging from “extremely uninteresting = 1” to “extremely interesting = 5.”

**3.2.3.2. Career Preferences.** We measure career preferences using a question in the PhD survey that asked respondents, “Putting job availability aside, how attractive do you personally find each of the following careers?” Careers included “startup job with an emphasis on research or development” and “established firm job with an emphasis on research or development” as well as other careers not considered in this study, such as university faculty. Respondents rated each career independently using a five-point scale ranging from “extremely unattractive = 1” to “extremely attractive = 5.” By explicitly asking respondents to disregard current labor market conditions, we seek to capture their career preferences independent of factors that may affect career

outcomes, such as perceived job availability (Stephan 2012, Roach and Sauermann 2017). We captured founder intentions separately by asking, “How likely are you to start your own company?” using a five-point scale ranging from “definitely will not = 1” to “definitely will = 5.”

Given that the ratings of career attractiveness are not mutually exclusive, we employ a three-step process to construct relative measures of career preferences. First, we code as founder types respondents who reported an intention of starting their own company (i.e., “likely will” or “definitely will”) and whose founder intention was equal to or greater than their attractiveness of working in an established firm.<sup>19</sup> Second, we code the remaining individuals who rated the attractiveness of working in a startup as greater than that of working in an established firm as joiner types and individuals who rated working in an established firm as more attractive than working in a startup as established firm types. This approach codes as joiner types individuals who prefer to work in a startup but who do not have founder intentions. Respondents who reported that working in a startup and an established firm were equally attractive are coded as indifferent types and are used as the comparison group in our regression analyses.<sup>20</sup> Third, individuals who were not attracted to working in either a startup or an established firm are coded as other types.<sup>21</sup> In our sample, 4.1% of respondents are founder types, 7.6% are joiner types, 41.7% are indifferent types, 36.6% are established firm types, and 10.0% are other types. An advantage of these broader career preferences over preferences for specific job attributes is that they likely reflect preferences for a more comprehensive bundle of job attributes offered by different types of firms as well as other unobserved factors such as social influences (Stuart and Ding 2006, Sørensen 2007, Azoulay et al. 2017) or occupational identity (Akerlof and Kranton 2000).

To provide insights into underlying differences between career preferences, we regress stated career preferences onto preferences for specific job attributes as well as other relevant variables. For simplicity, we combine founder and joiner types into a single category of startup types and compare them to established firm types. The results in Table 2 show that startup types exhibit significantly stronger preferences for autonomy and commercialization work activities and significantly weaker preferences for financial pay than established firm types. We find no difference in ability or risk tolerance. Consistent with our discussion in Section 2.3, these results indicate that startup types exhibit stronger preferences for nonpecuniary job attributes associated with startup employment and weaker preferences for financial compensation than established firm types (see also Roach and Sauermann 2015). Career preferences may also be shaped by the university context in which PhDs are trained (Stuart and Ding 2006, Azoulay et al.

**Table 2.** Comparison of Startup and Established Firm Career Preferences

Dependent variable	Startup (1) vs. established firm (0) career preferences
Ability	
<i>PhD department rank</i>	0.105 (0.077)

*Notes.* Logistic regression predicting startup (one if founder or joiner type) or established firm (zero) career preferences. Indifferent and other types are excluded to focus on theorized career preference types. Coefficients are log odds. Demographic characteristics are marital status and children. Degree field fixed effects for 14 fields of life sciences, chemistry, physics, engineering, and computer science. Job year fixed effects are for year of first job (2010–2016). Robust standard errors clustered on university in parentheses.

\* $p < 0.10$ ; \*\* $p < 0.05$ ; \*\*\* $p < 0.01$ .

2017). Indeed, startup types are more likely to come from university labs that encouraged careers in startups and where the advisor had founded a company and less likely to come from labs that encouraged careers in established firms (as reported in the PhD survey). Men and foreign-born PhDs who require a work visa are also more likely to be startup types (see also Roach et al. 2020).<sup>22</sup>

Despite the strong association between preferences for startup careers and for specific job attributes, one might be concerned that PhD students have limited information about industry jobs and may not see a clear distinction between working in startups or established firms. Using measures of ex ante expectations of the availability of job attributes from the PhD survey, we show in Online Table A4 that students expect significant differences between startups and established firms with respect to pay, R&D resources, job security, autonomy, and intellectual challenge. These differences are aligned with our characterization of startups and established firms in Section 2.1 and suggest that PhD students have reasonable expectations of differences between jobs in startups and established firms when stating their career preferences.

**3.2.4. Control Variables.** We control for several demographic characteristics, including gender, marital status, children, and whether respondents did postdoctoral

training prior to industry employment. Given that job choices of international students may be constrained by their need to secure a work visa after graduation (Roach and Skrentny 2019), we also use survey responses to distinguish graduates who are U.S. citizens or permanent residents from foreign PhDs who require a work visa for industry employment in the United States. We use PhD degree field fixed effects for 14 detailed fields within the broader fields of life sciences, chemistry, physics, engineering, and computer science.

Finally, employment outcomes depend not only on individuals' choices, but also on labor market conditions (see Section 2.5). To control for the general demand for human capital in startups, we include the annual amount of VC funding for early stage ventures (angel, seed, or series A) in the year that an individual started employment. Our rationale is that technology startups use a large share of their funding to hire employees such that the availability of VC funding should be positively correlated with startup job availability. We control for macroeconomic factors that may improve general industry job availability by including the annual U.S. gross domestic product (GDP) growth rate.<sup>23</sup> We explore the role of firm demand more directly in additional analyses using data on job offers as described in Section 4.4. Other measures used to explore mechanisms and to probe the robustness of our results are also discussed.

**3.2.5. Survey Measurement Issues.** There are general concerns when using survey data. One is common methods bias, which can occur when dependent and independent variables are measured using the same method (e.g., rating scales) and may result in inflated correlations between variables (Podsakoff et al. 2003). This is not a concern for our study because our dependent and independent variables are measured using different scales or data sources, such as LinkedIn. A second concern with self-reported survey measures is that respondents may overstate preferences that seem socially desirable, especially in the eyes of peers or advisors. We partly addressed this concern by assuring respondents in the survey invitation that all responses would be kept strictly confidential. Whereas any remaining social desirability bias may affect descriptive statistics (e.g., shares of founder or joiner types), it would affect regression analyses only to the extent that it is associated with unobserved respondent characteristics that are correlated with other featured variables. Our rich set of control variables should capture much of this typically unobserved heterogeneity.

## 4. Results

We first present key descriptive patterns (Section 4.1), followed by our main analyses examining the roles of ability and preferences in predicting startup employment both separately (Section 4.2) and jointly (Section 4.3). Next, we investigate the role of startup demand using more detailed data on startup job applications and job offers (Section 4.4). We then provide supplemental analyses that relate our findings to the literature on startup earnings and compensating differentials as well as provide additional evidence on ex post job attributes

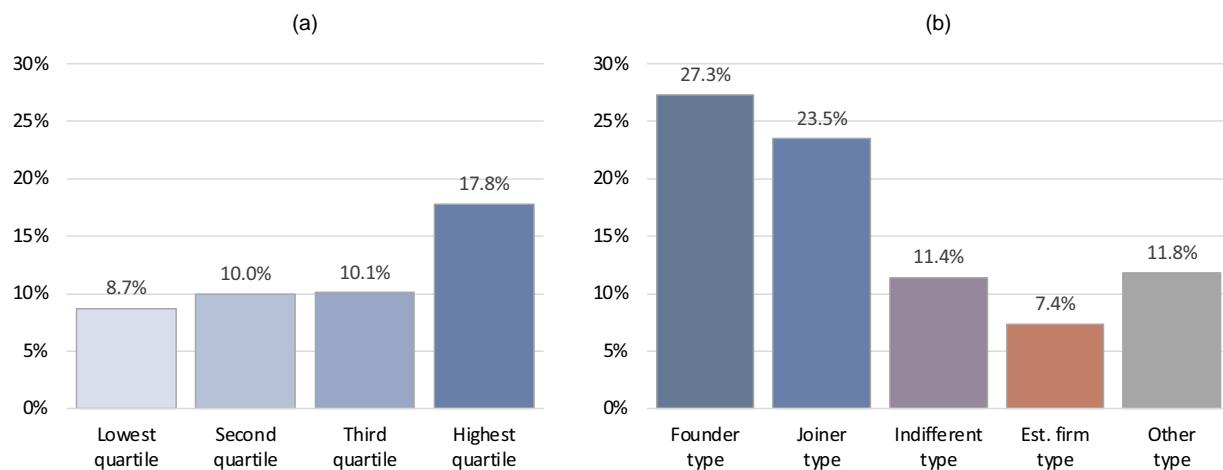

and workers' reasons to take startup jobs (Section 4.5). Finally, we discuss the robustness of our results (Section 4.6).

### 4.1. Descriptive Results

Table 1 reports summary statistics for the full sample as well as by employment type and career preferences. Across the full sample, 11.6% of graduates are employed in startups. The average ability of startup employees as measured by PhD department rank is higher than the average ability of established firm employees ( $-13.36$  versus  $-16.80$ ; smaller values indicate higher rank). Panel (a) of Figure 2 plots the share of startup employees for each quartile of the ability distribution, showing that the share in the highest ability quartile (17.8%) is roughly twice as large as in the lowest ability quartile (8.7%), illustrating that ability has a positive relationship with startup employment in our sample. Panel (b) of Figure 2 shows that a higher share of founder (27.3%) and joiner (23.5%) types work in a startup compared with a much lower share of established firm types (7.4%). These patterns indicate a strong relationship between career preferences and employment outcomes.

As per Section 2.4, our model of ability and career preferences as two distinct dimensions is most relevant if they are not strongly correlated. Confirming that this condition is met, Table 1 shows that there is no significant difference in PhD department rank between joiner and established firm types ( $t$ -statistic = 1.124,  $p$  = 0.262) or founder and established firm types ( $t$ -statistic =  $-0.551$ ,  $p$  = 0.582). A more detailed contingency table analysis also shows no significant association between ability quartiles and career preferences (Online Table A5).

**Figure 2.** (Color online) Share of Startup Employees by Ability Quartile (a) and Career Preferences (b)

*Notes.* (a) Startup employee share by ability quartile. (b) Startup employee share by career preference.

Notes. Logistic regressions predicting employment in an early stage startup (1 if age  $\leq 5$  years and size  $\leq 50$  employees) or established firm (0 if age  $> 5$  years and/or size  $> 50$  employees). Coefficients are log odds. Demographic characteristics are gender, marital status, children, prior postdoc, foreign worker status. Degree field fixed effects for 14 fields of life sciences, chemistry, physics, engineering, and computer science. Labor market conditions are log annual early stage VC funding and annual U.S. GDP growth rate. Robust standard errors clustered on university in parentheses.

\* $p < 0.10$ ; \*\* $p < 0.05$ ; \*\*\* $p < 0.01$ .

## 4.2. Ability and Preferences as Predictors of Startup Employment

We now examine how ability and ex ante preferences relate to ex post startup employment. Table 3 presents logistic regressions predicting whether graduates' first industry job is in an early-stage startup (coded as one) or an established firm (coded as zero).<sup>24</sup> All models control for individuals' demographic characteristics, degree field, and labor market conditions. Robust standard errors clustered on university are reported in parentheses.

Following the flow of our conceptual discussion, we first examine ability and preferences separately. As per Section 2.2, ability-sorting theories focusing on productivity and income predict that high-ability workers are less likely to work in resource-constrained startups. Contrary to this prediction, columns (1)–(4) show that higher ability employees (i.e., PhDs from higher ranked university departments) are more likely to work in a startup. Estimates from Model 3, our preferred specification, indicate that a one standard deviation (SD) increase in PhD department rank is associated with a 32% higher likelihood of startup employment.<sup>25</sup>

Model 1 also includes preferences for specific job attributes. Individuals who are more risk-tolerant, have a

stronger preference for autonomy, and express a greater interest in commercialization activities are more likely to work in a startup, whereas individuals with a stronger preference for managerial activities are less likely to work in a startup.<sup>26</sup> A preference for financial pay has a weak negative but insignificant relationship with startup employment. Model 2 includes both career preferences and preferences for specific job attributes. Compared with individuals who are indifferent between working in a startup or an established firm (omitted category) founder and joiner types are significantly more likely to work in a startup, whereas established firm types are significantly less likely. The reduced significance of preferences for autonomy and commercialization suggests that they are mediated through career preferences (see Section 2.3), whereas risk tolerance is partially mediated. The strong main effects of career preferences in Model 2 indicate that they are important in their own right and may capture preferences for other job attributes not included in our model as well as other factors such as social influences and individuals' career identity (see Section 3.2.3).

Model 3 excludes job attribute preferences to focus on career preferences as highlighted in our conceptual

discussion. Using this regression as our preferred model, we find that, relative to indifferent types, founder types are nearly three times as likely (odds ratio of 2.942) and joiner types nearly twice as likely (odds ratio of 1.915) to work in a startup, whereas established firm types are about half as likely (odds ratio of 0.576).<sup>27</sup> The estimates of ability are not sensitive to the inclusion of career preferences, reflecting that ability and career preferences are not correlated. The results for ability and career preferences are robust to controlling for the nature of R&D activities and other ex post job attributes (Online Table C2). We find no significant differences in employment outcomes by gender, marital status, or the number of children in our sample (Online Table A4). Foreign graduates requiring visa sponsorship are less likely to work in a startup (see also Roach and Skrentny 2019).<sup>28</sup>

An important concern with measuring ability using PhD department rank is that it may also reflect aspects of the entrepreneurial context of the department, university, or region. For example, PhDs from MIT and Stanford are not only higher ability but are also located in entrepreneurial universities and regions that may foster startup employment. To account for this, Model 4 controls for whether individuals did their PhD at a university in an entrepreneurial region (i.e., Boston and San Francisco) as well as whether their advisor founded a startup and the degree to which university laboratory norms encouraged startup employment. As expected, PhDs from universities in entrepreneurial regions are more likely to work in a startup. Even after controlling for these factors, however, PhD department rank remains positive and highly significant, suggesting that our results are not driven by university or region effects.<sup>29</sup>

As discussed in Section 3.2.2, an additional concern with the PhD department rank measure is that it does not vary across individuals within a department. To account for this, we constructed an alternative individual-level ability measure through a regression approach that uses observable signals of ability including publications, patents, research awards, and starting

pay (see Online Appendix B for details). Model 5 shows that this ability index also significantly predicts startup employment. The coefficients of career preferences are largely unchanged, indicating that our key results on both ability and preferences are robust to using two very different proxies for ability. We report additional robustness checks in Section 4.6.

### 4.3. The Joint Role of Ability and Preferences

Building on the conceptual discussion summarized in Figure 1, we now examine the joint roles of ability and career preferences. To compare different combinations of ability and preferences (i.e., high-ability startup types, low-ability established firm types, etc.), we first construct categorical variables for high (76%–100%) and low (0%–25%) ability workers and combine the two middle quartiles into an average ability category. To simplify the analysis of career preferences, we combine founder and joiner types into startup types. We then construct categorical variables for each combination of ability and career preferences. This approach results in 12 categorical variables that reflect all possible combinations of ability (high, average, and low) and career preferences (startup, indifferent, established firm, and other types). Regressions using these categorical variables estimate the combined effects of ability and preferences, including potential reinforcing and offsetting effects (see Section 2.4).<sup>30</sup> Table 4 summarizes results from logistic regressions that compare startup employment outcomes between our four featured ability–preference combinations; each column reports the comparison as odds ratios relative to a different omitted combination to facilitate the interpretation (the underlying logistic regressions are available from the authors).

First, we predicted in Section 2.4 that high-ability established firm types should be least likely to work in a startup because of the reinforcing productivity and preference benefits from established firm employment. Although high-ability established firm types (column (2)) are less likely to work in a startup than both high- and low-ability startup types (odds ratios of 0.280 and

**Table 4.** Joint Effects of Ability and Preferences on Startup Employment

	High ability–Startup type (1)	High ability–Est. firm type (2)	Low ability–Startup type (3)	Low ability–Est. firm type (4)
High ability–Startup type	—	0.280 ( <i>p</i> -value = 0.000)	0.481 ( <i>p</i> -value = 0.039)	0.146 ( <i>p</i> -value = 0.000)
High ability–Est. firm type	3.567 ( <i>p</i> -value = 0.000)	—	1.715 ( <i>p</i> -value = 0.060)	0.521 ( <i>p</i> -value = 0.037)
Low ability–Startup type	2.079 ( <i>p</i> -value = 0.039)	0.583 ( <i>p</i> -value = 0.060)	—	0.304 ( <i>p</i> -value = 0.000)
Low ability–Est. firm type	6.848 ( <i>p</i> -value = 0.000)	1.920 ( <i>p</i> -value = 0.037)	3.293 ( <i>p</i> -value = 0.000)	—

*Notes.* Table reports odds ratios of working in a startup from a series of logistic regressions for each featured ability–preference combinations (column title) relative to other ability–preference combinations (rows). For example, high-ability startup types (column (1)) have 3.567 greater odds of working in a startup compared with high-ability established firm types. Models also included combinations for average ability and indifferent and other career preference types as well as controls for demographic characteristics (gender, marital status, children, prior postdoc, foreign worker status), labor market conditions (log annual early stage VC funding and annual U.S. GDP growth rate), and degree field fixed effects (14 fields of life sciences, chemistry, physics, engineering, and computer science). Robust standard errors clustered on university.

0.583, respectively), they are more likely to work in a startup than low-ability established firm types (1.920 greater odds). This is consistent with the earlier finding of a positive coefficient of ability in Table 3, which we explore in more detail.

Next, the predictions regarding high-ability startup types were ambiguous because these individuals face a stronger trade-off between the preference benefits from working in a startup and the higher opportunity costs of forgoing greater productivity and pay in an established firm. Column (1) suggests that the benefits outweigh the costs: high-ability startup types are significantly more likely to work in a startup than all other ability-preference combinations. We note that the finding that high-ability startup types are more likely to work in a startup than low-ability startup types cannot be explained by supply-side considerations alone; we explore the role of startup demand for high-ability workers as a potential explanation. Finally, low-ability startup types (column (3)) are more likely to work in a startup than both high- and low-ability established firm types (1.715 and 3.293 greater odds, respectively), likely reflecting their higher expected preference benefits from startup employment.

Figure 3 presents the predicted likelihoods of working in a startup for each ability-preference combination, visualizing how the joint effects of ability and preferences add up to considerable differences in employment outcomes. For example, the likelihood of high-ability startup types working in a startup is 29.6%, whereas the likelihood of low-ability established firm types is 6.2%.

#### 4.4. Startup Job Applications and Job Offers

Our main results show that ability and preferences in combination are important in explaining who works in a startup. However, our conceptual framework implies

**Figure 3.** (Color online) Predicted Probability of Working in an Early Stage Startup by Ability-Preference Combination

	Indifferent	Est. firm
Startup type	type	type
High ability	29.6%	18.0%
Avg. ability	21.5%	10.1%
Low ability	17.4%	6.2%

*Notes.* Predicted probabilities are from a logistic regression that includes categorical variables for different ability-preference combinations (e.g., high-ability startup type). Ability categories are based on quartiles of PhD department rank: high ability (76%–100%), average ability (26%–75%), low ability (1%–25%). Startup type combines founder and joiner types. Model also includes controls for demographic characteristics (gender, marital status, children, prior post-doc, foreign worker status), degree field fixed effects (14 fields of life sciences, chemistry, physics, engineering, and computer science), and labor market conditions (log annual early stage VC funding and annual U.S. GDP growth rate).

that ability and preferences may play different roles at different stages of the job market process, reflecting two different kinds of selection: individuals should self-select into applying to startup jobs based primarily on preferences, whereas startups should select applicants based primarily on ability when making job offers.

To gain deeper insights into the distinct roles of ability and preferences in the job market process, we utilize a question that asked respondents in the employment survey, “When you were searching for your first industry job, did you apply for and/or receive job offers from startups or established companies?” Respondents answered yes or no separately for “applied for at least one startup job” and “received at least one startup job offer.” Among the 1,371 PhDs who responded to this question, 66% of founder types and 58% of joiner types applied to at least one startup job compared with 47% of indifferent types and 40% of established firm types.<sup>31</sup> For comparison, 96.5% of respondents reported applying to at least one established firm job, and 95.0% of these received at least one offer with only minor differences by career preferences. These patterns confirm that established firms are the default employment option.

In the first stage of the labor market process, workers choose whether to apply to startup jobs. We examine this stage using the startup job application measure as the dependent variable (Table 5, column (1)). Ability-based theories of job choice predict that high-ability workers are less likely to apply to startup jobs given expectations of lower productivity and income (Section 2.2), whereas preference-based theories predict that founder and joiner types are more likely to apply to startup jobs (Section 2.3). Although the coefficient of ability is negative, it is not statistically significant. As expected, founder and joiner types are significantly more likely to apply to startups than indifferent types, whereas established firm types are less likely to apply. The finding that ability does not predict startup job applications may partly indicate that startups are attractive to many high-ability workers, perhaps because of opportunities to work on cutting-edge technologies. We explore this possibility in Section 4.5.

In the second stage, startups select among applicants to make job offers. Consistent with our expectation (Section 2.5), column (2) shows that, conditional upon applying, higher ability workers are significantly more likely to receive a startup job offer (i.e., startups make offers to PhDs from higher ranked departments). Although founder types are somewhat more likely to receive a startup job offer, we do not find a difference across other types, suggesting that startups make offers based on employee ability rather than preferences. Even though startups may rely more on high-ability workers to commercialize cutting-edge technologies, making offers based on ability is likely not unique to startups because high-ability workers should be more productive in all types of firms.

**Table 5.** Startup Job Search Stages

\* $p < 0.10$ ; \*\* $p < 0.05$ ; \*\*\* $p < 0.01$ .

As such, the more interesting insight emerges when considering the results of columns (1) and (2) in combination: given that graduates apply to startups based on career preferences rather than ability, the applicant pool includes enough high-ability individuals such that startups can cherry-pick talented workers despite offering lower complementary assets and pay.

In the final stage, individuals who received a startup job offer choose whether to accept, leading to the observed employment outcomes. Column (3) shows that, conditional upon receiving a startup job offer, high-ability workers are more likely to work in a startup. Again, this result is contrary to the prevailing view that high-ability workers choose jobs in established firms over startups (Section 2.2). As expected, the decision to accept a startup job offer is also explained by career preferences: founder and joiner types are significantly more likely to work in a startup, whereas established firm types are less likely.

Although our interpretation of column (3) assumes that workers choose between offers from startups and established firms, some workers did not apply to established firms or did not receive established firm job offers. Column (4) drops these cases to focus on workers with offers from both startups and established firms. The results confirm that high-ability workers are more likely to work in a startup even when they have offers from established firms. Although the coefficients of founder and joiner types are not statistically significant compared with indifferent types, joiner types are significantly more likely to work in a startup compared with established firm types. The weaker coefficients of startup career

preferences may be in part because of lower variability in the subsample of workers who applied to both startup and established firm jobs given that this sample excludes startup types who chose not to apply to established firms as well as established firm types who chose not to apply to startups (see column (1)).

#### 4.5. Evidence on Earnings, Ex Post Job Attributes, and Reasons for Job Choice

The results presented thus far show that high-ability PhDs are more likely to work in early-stage technology startups, and the strong preference-based self-selection suggests that many do so for nonpecuniary benefits. In the following, we provide additional evidence on the assumptions of our conceptual discussion (Section 2) and explore potential mechanisms underlying the main results.

**4.5.1. Earnings of Startup and Established Firm Employees.** A key assumption of our conceptual discussion is that startups have lower resources and pay lower salaries, creating a potential trade-off for high-ability startup types who should expect greater preference-based benefits in startups but greater productivity and financial returns in established firms (Section 2.4). Although our findings suggest that the preference benefits outweigh the opportunity costs for many high-ability startup types (consistent with Stern 2004), an alternative explanation is that high-ability scientists and engineers may be paid more in startups to compensate for startups' lower complementary assets (Bhaskarabhatla et al. 2021). To examine this alternative explanation and verify a key

assumption of our model, we now compare the earnings of startup and established firm employees.

In the employment survey, we asked respondents, “What was your total starting annual compensation (in U.S. dollars), including base salary, annual bonuses, etc.?” Respondents reported their starting compensation on a sliding scale ranging from \$0 to \$500k. We also asked respondents whether they received equity or stock options from their employer (Y/N) to control for this potential compensation mechanism. In our sample, 74.8% of startup employees and 41.3% of established firm employees reported receiving equity or stock options. Even though the share of startup employees receiving equity is higher, we note that startup equity is very risky and typically does not have monetary value unless the venture has a successful liquidity event, whereas publicly traded established firms’ stock options are tied to the current share price and, thus, have a known monetary value (see also Section 2.2).

Table 6 reports ordinary least squares (OLS) regressions of (log) starting earnings. Column (1) estimates the difference in earnings between startup and established firm employees controlling for only demographic characteristics

and degree field fixed effects. Startup employees earn 16% less than established firm employees. This supports the underlying premise of our conceptual discussion and is also consistent with prior results using administrative data (Haltiwanger et al. 2013, Ouimet and Zarutskie 2014, Burton et al. 2018, Sorenson et al. 2021). Column (2) includes measures of ability and career preferences, which are typically unobserved in administrative data. As expected, higher ability individuals earn significantly more: a one-SD increase in PhD department ranking is associated with 5.6% higher earnings. The estimated earnings gap between startup and established firm employees remains remarkably stable with the former earning 17% less than their peers in established firms. Career preferences have no significant relationship with earnings. These results are robust to controlling for job attributes in Online Table C2. Although much of the prior literature interprets lower earnings in startups as evidence of lower startup human capital, our earlier finding that high-ability employees are more likely to work in a startup suggests that the pay difference instead reflects a taste-based compensating differential.

**Table 6.** Earnings of Startup and Established Firm Employees

*Notes.* OLS regressions of starting pay in first job and current pay. Dependent variable for Models 1–4 is measured from a question in the employment survey that asked respondents to report their total starting compensation (including salary and bonuses) in their first job. Model 1 is a baseline specification with control variables, and Model 2 includes ability and career preferences. Model 3 restricts the sample to established firm employees, and Model 4 restricts the sample to startup employees. Model 5 replaces starting pay as the dependent variable with current pay for workers with at least five years of industry work experience to compare long-term earnings of employees whose first job was in a startup versus an established firm. Model 6 includes the interaction between startup employment and (mean centered) PhD department rank. Demographic characteristics are gender, marital status, children, prior postdoc, foreign worker status. Degree field fixed effects for 14 fields of life sciences, chemistry, physics, engineering, and computer science. Labor market conditions are log annual early-stage VC funding and annual U.S. GDP growth rate. Robust standard errors clustered on university in parentheses.

\**p* < 0.10, \*\**p* < 0.05, \*\*\**p* < 0.01.

Columns (3) and (4) estimate regressions for the split samples of startup and established firm employees to examine whether the roles of ability and preferences differ between employer types. Ability continues to predict higher earnings in established firms (column (3)), whereas the relationship is weaker and insignificant in startups (column (4)). To illustrate, the predicted starting pay of established firm employees in the highest ability quartile is \$117,151 compared with \$98,505 for employees in the lowest ability quartile. A stronger relationship between ability and earnings in established firms is consistent with our assumption that large firms possess greater resources to compensate higher ability workers for their greater productivity (see Section 2.2). Early-stage startups, on the other hand, are resource-constrained and, thus, unable to offer higher ability workers extra pay to compensate for their greater productivity (which only generates financial returns in the future if the venture is successful). Whereas early stage startup employees might also be compensated through equity, the results show that startup employees who receive equity do not earn less, suggesting that the role of equity may be more nuanced than to compensate startup employees for lower earnings.

Although one might expect that established firm types require higher pay in startup employment to compensate for the misalignment with their career preferences, the lack of significant coefficients for career preferences in column (4) suggests that this is not the case. Our interpretation is that startups' resource constraints limit their ability to offer higher pay, and thus, established firm types who find startup pay too low instead work for higher pay in established firms. This, in turn, suggests that the small share of established firm types who decide to work in startups despite receiving lower pay may do so because they expect additional nonpecuniary benefits in startup employment. We explore this possibility using additional survey questions in Section 4.5.3.

Perhaps more importantly, the result that high-ability workers earn more in established firms but not in startups suggests that they take a greater wage discount to work in startups than low ability workers. This is consistent with our premise that the opportunity costs of startup employment are greater for high-ability workers (Section 2.2). To verify this, we estimated earnings by ability quartiles for startup and established firm employees, including a broad set of controls (regression results available from the authors). Figure 4 shows that startup employees in the highest ability quartile earn approximately \$24,076 (20.6%) less than their peers in established firms, whereas startup employees in the lowest ability quartile earn \$12,465 (12.7%) less than their peers in established firms.

Although these results suggest that high-ability workers accept lower earnings in exchange for nonpecuniary benefits from working in startups, the findings do not rule out that they may also take startup jobs in expectation

of greater financial compensation in the future. For example, individuals may expect that startup employment enables them to develop their human capital faster than employment in established firms, potentially leading to higher future pay (Campbell 2013). They may also expect that as the startup grows and secures funding they will be promoted and see their earnings rise more rapidly than they would in an established firm (see Sorenson et al. 2021). If such mechanisms are important to workers' startup job choice, then we would expect the earnings of startup employees to catch up and eventually surpass the earnings of established firm employees.<sup>32</sup>

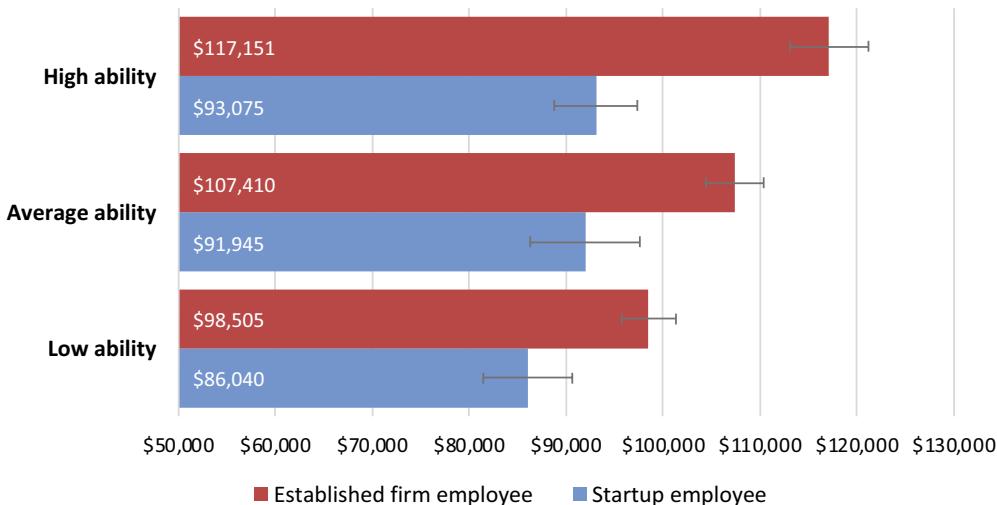

To examine earnings trajectories, we utilize additional data for the subsample of workers who have been employed at least five years and who responded to a subsequent wave of the employment survey and reported their current earnings ( $n = 986$ ).<sup>33</sup> Column (5) replaces starting pay with current pay as the dependent variable, also controlling for the number of years in industry employment (five to nine years in our sample). We find that current pay of workers whose first job was in a startup is 14.7% less than that of workers whose first job was in an established firm, indicating that the pay gap remains large and significant even after at least five years of industry employment. A final analysis confirms that this is the case also for high-ability workers: the interaction between startup employment and (mean-centered) PhD department rank is not statistically significant (column (6)). Overall, whereas we cannot rule out that some individuals chose to work in a startup at least in part because of expectations of higher future earnings, the observed persistently lower earnings are more consistent with workers receiving nonpecuniary benefits from startup employment that compensate for lower pay (Hamilton 2000, Stern 2004).<sup>34</sup>

#### 4.5.2. Ex Post Job Attributes in Startups and Established Firms.

In Section 2.2, we contend that resource constraints hinder startups' ability to offer higher pay (as shown in the prior section) and also limit startups' ability to offer complementary assets that increase worker productivity. At the same time, we suggest that startups offer nonpecuniary job attributes, such as autonomy and opportunities to work on cutting-edge R&D projects, that may enable them to attract high-ability workers despite resource constraints (Section 2.3). We now verify the premises of these arguments using questions from the employment survey that asked respondents about different ex post job attributes.

To examine whether startups are indeed more resource-constrained, we asked respondents to rate the "current level of resources for your R&D activities" on a four-point scale from "extremely insufficient = 1" to "more than sufficient = 4." Column (1) in Table 7 regresses this measure onto startup employment, also controlling for degree field

**Figure 4.** (Color online) Predicted Starting Pay by Ability and Employment

*Notes.* Predicted from an OLS regression of starting pay. Ability categories are based on quartiles of PhD department rank: high ability (76%–100%), average ability (26%–75%), low ability (1%–25%). Model also includes controls for demographic characteristics (gender, marital status, children, prior postdoc, foreign worker status), degree field fixed effects (14 fields of life sciences, chemistry, physics, engineering, and computer science), labor market conditions (log annual early stage VC funding and annual U.S. GDP growth rate), and stock options.

and job year fixed effects. Startup employees have significantly lower resources than established firm employees, consistent with our conceptual premise.

Turning to nonpecuniary job attributes, we first examine whether startups offer employees greater autonomy in their work. We asked respondents how much influence they have over choosing which R&D projects to work on, ranging from “no influence = 1” to “complete influence = 5.” Consistent with our conceptual discussion, column (2) shows that startup employees report significantly more autonomy than established firm employees. Next, we asked respondents the extent to which they agreed that their R&D activities are “cutting-edge (i.e., advanced areas of science and/or technology)” and “highly intellectually challenging,” each rated on a five-point scale from “strongly disagree = 1” to “strongly agree = 5.” Startup employees more strongly agree that

their R&D is cutting-edge (column (3)) and highly intellectually challenging (column (4)) than established firm employees. Of course, startups are not the only place to work on cutting-edge technologies: a quarter of established firm employees also strongly agree that their R&D work is cutting-edge. However, this share is lower than that among startup employees, consistent with our premise that established firms have a more diverse portfolio of R&D projects.

**4.5.3. Stated Reasons for Job Choice and for Working in a Startup.** We complement the evidence on earnings and ex post job attributes with data on individuals’ ex post stated reasons for taking their current job. In particular, the employment survey asked workers to select “very important reasons” for choosing their first job, offering a number of pecuniary and nonpecuniary job attributes. Regressions

**Table 7.** Attributes of First Job in Startups vs. Established Firm

Dependent variable	R&D resources (1)	Autonomy (2)	Cutting edge (3)	Intellectually challenging (4)
Startup employee	-0.640*** (0.162)	0.711*** (0.110)	0.520*** (0.140)	0.450** (0.190)
Degree field fixed effects	Y	Y	Y	Y
Job year fixed effects	Y	Y	Y	Y
Log-likelihood	-1,151.958	-1,770.128	-1,591.382	-1,442.482
Observations	1,059	1,258	1,128	1,128

*Notes.* Ordered logistic regressions predicting ex post job attributes. Coefficients are ordered log odds. DV in Model 1 is respondents’ assessment of their “current level of resources for R&D activities” on a four-point scale from “extremely insufficient = 1” to “more than sufficient = 4.” DV in Model 2 is respondents’ assessment of how much influence they have over choosing which R&D projects to work on from “no influence = 1” to “complete influence = 5.” Model 3 is respondents’ assessment of the extent to which they agreed that their R&D is “cutting-edge (i.e., advanced areas of science and/or technology)” on a five-point scale from “strongly disagree = 1” to “strongly agree = 5.” DV in Model 4 is respondents’ agreement that their current R&D is “intellectually challenging” on a five-point scale from “strongly disagree = 1” to “strongly agree = 5.” Control variables are degree field fixed effects for 14 fields of life sciences, chemistry, physics, engineering, and computer science, and job year fixed effects (2010–2016). Robust standard errors clustered on university in parentheses.

\* $p < 0.10$ , \*\* $p < 0.05$ , \*\*\* $p < 0.01$ .

comparing these reasons between startup and established firm employees (Table 8) reinforce the patterns reported in prior sections as well as our discussion of potential drivers of career preferences (Section 2.3): startup employees are significantly less likely to state higher compensation and job security as very important reasons for choosing their job than established firm employees and are significantly more likely to report opportunities to work on cutting-edge technologies as having been very important.<sup>35</sup> Career advancement is mentioned frequently by both startup and established firm employees with no significant difference between the two groups.

We also asked startup employees specifically whether “the startup idea seemed very promising” was a very important reason for choosing their job. Approximately 66% of respondents across career preference types indicated that it was. Thus, whereas our earlier results suggest that workers are drawn to startup employment by a number of job attributes associated with the startup setting in general, perceived startup quality likely also plays a role in their decision to accept a given startup offer (Bryan et al. 2022). Indeed, startup quality may not be independent of those other attributes, for example, if high-quality startups offer greater opportunities to work on cutting-edge technologies. We note that this reason is not cited more frequently by high-ability workers, providing no evidence that high-ability workers are more likely to join startups because they are (or believe to be) better able to identify the most promising new ventures.<sup>36</sup> That said, our data do not allow us to determine whether and how workers differ in their ability to assess startup quality and whether any such differences explain employment choices.

In a final analysis, we seek to understand whether reasons for joining startups differ between career preference types. Recall from Section 2.3 that founder types might choose to work in a startup specifically to build their entrepreneurial skills and learn to be a founder (Gompers et al. 2005, Sørensen 2007, Elfenbein et al. 2010), whereas joiner types are likely drawn to startup employment for reasons other than becoming a founder.

Our conceptual framework also suggests that both founder and joiner types should consider startup employment a particularly good fit with their career preference, whereas established firm types should not. Finally and related to the prior analysis, we speculated that high-ability established firm types might work in startups because of opportunities to work on cutting-edge technologies.

We explore these reasons using a question that asked startup employees to select important reasons for working in a startup, including “I wanted to learn about entrepreneurship to help me startup my own company one day,” “I thought working in a startup would be a better fit for me than other job options,” and “I am interested in the specific technology or industry.” Among founder types, 63.2% reported learning about entrepreneurship as an important reason to work in a startup compared with only 35.1% of joiner types, 37.5% of indifferent types, and 20.4% of established firm types, providing direct evidence that many aspiring founders expect startup employment will provide a valuable learning experience. We also find that a higher share of founder (78.9%), joiner (73.0%), and indifferent (74.0%) types report that working in a startup was a better fit for them compared with established firm types (53.1%). The share of startup employees who reported a strong interest in the startup’s technology is relatively high across preference types (63.2% of founder types, 73.0% of joiner types, 73.0% of indifferent types, and 67.3% of established firm types), reinforcing again that opportunities to work on interesting R&D projects make early stage startups attractive to scientists and engineers. The number of established firm types working in startups is small, but the fact that most of them indicate an interest in the startup’s particular technology suggests a potential explanation for why they joined a startup despite their ex ante preference to work in an established firm and lower earnings. We also note that the similarities between (ex ante) joiner types and indifferent types working in startups suggest that the latter revealed a career preference for startup employment, possibly

**Table 8.** Ex Post Stated Reasons for Choosing First Job

Dependent variable	Higher compensation (1)	Job security (2)	Career advancement (3)	Cutting-edge projects (4)
Startup employee	−1.223*** (0.236)	−1.689*** (0.289)	−0.089 (0.170)	0.648*** (0.157)
Degree field fixed effects	Y	Y	Y	Y

Log-likelihood	−786.695	−677.207	−846.724	−818.085
Observations	1,237	1,237	1,237	1,237

*Notes.* Logistic regressions predicting ex post reasons for choosing first job. Coefficients are log odds. Dependent variables are from a question that asked respondents to indicate “very important reasons” for choosing their first job (one if yes, zero if no). Control variables are degree field fixed effects for 14 fields of life sciences, chemistry, physics, engineering, and computer science, and job year fixed effects (2010–2016). Robust standard errors clustered on university in parentheses.

\* $p < 0.10$ ; \*\* $p < 0.05$ ; \*\*\* $p < 0.01$ .

indicating that a large share of startup employees (approximately 56%) are joiner types.

Although self-reported earnings, job attributes, and reasons for job choice should be interpreted with caution, the patterns reported in this section are largely consistent with our conceptual discussion as well as our interpretation of the main results. First, data on earnings expectations, starting earnings, earnings trajectories, and stated reasons for job choice suggest that financial returns do not play a major role in startup job choice. Instead, the evidence points to nonpecuniary benefits as the driving factor. Of course, workers likely still consider financial aspects when weighing the pros and cons of different job options (see Section 2.4), and some may still take startup positions in part because of expectations of higher (long-term) income. Second, although startups offer lower earnings and resources for research, they also offer greater opportunities to work on cutting-edge technologies, consistent with our portrayal of the respective R&D portfolios and human capital demands. This result also highlights the value of thinking about a broader range of complementarities between human capital and firm attributes (see Section 2.2). Third, our results regarding levels of various job attributes as well as self-reported reasons for taking startup employment suggest that preferences related to a range of nonpecuniary factors are indeed important to understanding why many talented workers chose startup jobs. This, in turn, helps us understand why resource-constrained early stage startups can hire high-ability individuals from a relatively large and diverse pool of applicants (Section 4.4) despite offering lower financial compensation.

#### 4.6. Robustness Checks

Before we conclude, we summarize a series of robustness checks. First, we verified the robustness of our results to different constructions of the dependent variable of startup employment (Online Table C1). Our results are robust to excluding small established and large young firms, to restricting established firms to the elite top 10% in size, and to excluding growth-stage ventures (series B or higher) using data from Crunchbase.

Second, we verified that our results are not an artifact of the construction of relative career preference types by using the baseline career attractiveness measures described in Section 3.2.3. The results are consistent with the main findings: individuals who rated startup careers as “attractive” or “extremely attractive” are significantly more likely to work in a startup, whereas those who rated established firm employment as “attractive” or “extremely attractive” are significantly less likely to work in a startup.

Finally, we replicated the main startup employment and earnings analyses controlling for ex post job characteristics and the nature of R&D activities (Online Table C2), providing more nuanced insights into the role of

employer type (i.e., startups versus established firms) rather than the specific job. The results for ability and career preferences remain substantively unchanged, supporting our premise that firm types are a useful level of analysis.

## 5. Discussion

Early stage startups require talented scientists and engineers to commercialize new technologies. However, these individuals likely also have employment options in established firms that offer greater complementary assets and higher pay. Although theories of job choice that focus on productivity and income suggest that resource-constrained startups struggle to hire high-ability workers, longitudinal data from U.S. PhD graduates show the opposite: startups are able to hire high-ability workers despite paying them approximately 20% less than established firms. Consistent with theories of preference-based sorting, we find that career preferences expressed during graduate school strongly predict startup employment, suggesting that many individuals join startups because of expected nonpecuniary benefits that compensate them for lower startup pay. Further analyses using data on job applications and offers suggest that the pool of workers drawn to startup employment is large enough that startups can make job offers selectively to the most talented scientists and engineer. Our analyses account for a broad range of controls, and the results are robust to using alternative measures and specifications.

Despite these novel findings, our analyses are not without limitations. First, our sample of early career PhDs is relatively homogenous with respect to age, experience, and education. Although this allowed for a sharper focus on the constructs and mechanisms of interest, the sample may not be representative of the broader population of startup employees or of all types of startups. For example, it is conceivable that PhDs focus less on pecuniary benefits or are more attracted to working on cutting-edge technologies relative to employees with other degrees. Future research could study such differences using data from populations that are more diverse with respect to education and career stage. At the same time, we expect the findings that employment outcomes are driven by both preferences and ability and that preference-based benefits may offset opportunity costs for high-ability individuals apply more generally across contexts and different samples.

Second, whereas our analyses suggest that preferences for startup employment play an important role in explaining why high-ability workers join startups despite lower pay, we cannot identify all potentially relevant benefits of startup employment. For example, it is conceivable that some individuals choose startup employment based in part on expectations that startup

equity will result in great personal wealth if the venture is successful or that startup employment offers unique opportunities to build human capital (Campbell 2013, Sorenson et al. 2021). That said, we conceptualized startup employment as entailing a distinct bundle of job attributes, and our results suggest that startup career preferences matter even if we cannot identify all of the specific factors that attract individuals to startups.

Third, although our conceptual discussion focuses on labor supply, we also consider the implications of firms' demand for high-ability workers. Future research could gain even deeper insights by using more fine-grained measures of demand, such as open positions in different kinds of jobs, perhaps even at the level of individual firms. Relatedly, we note that our results are based on realized employment outcomes. For example, our finding that a disproportionate share of startup employees are high-ability may partly reflect that our sample includes more promising startups that were successful in hiring. More comprehensive data on the demand side of the labor market—including firms that fail to hire—could be used to examine such potential selection effects related to the quality of firms rather than the ability of workers (Bryan et al. 2022).

In addition to our contributions to the entrepreneurship literature as discussed in the introduction, our study has implications for founders, managers, and policy makers. First, several studies show that attracting and retaining human capital is a critical hurdle for founders in their efforts to build successful ventures (Baron et al. 1996, Hsu 2009, Wasserman 2012). Our results suggest that early stage technology startups can overcome these challenges by appealing to individuals who have a strong preference for working in an entrepreneurial environment. Although these individuals appear willing to "pay" to work in startups (Stern 2004), this does not necessarily come free to their employers. Rather, some of the features that attract workers to startups may need to be managed carefully and may involve costs of their own, such as higher degrees of autonomy (Gambardella et al. 2020).

Second, selection based on preferences suggests that successful startups may face challenges in keeping early employees if growth leads to changes in organizational features and job characteristics away from those that attracted employees to startups in the first place. Similar concerns are raised by large firms' efforts to "acqui-hire" science and engineering human capital by buying startups: it may well be that employees are more likely to leave after an acquisition if they initially joined the startup because they did not have a taste for a corporate environment (Kim 2020, Ng and Stuart 2022). These concerns provide further justification for efforts to preserve an entrepreneurial culture as startups grow or to create entrepreneurial units within larger corporations.

Finally, we find that a significant share of individuals with founder or joiner preferences take employment in established firms. Although future research is needed to understand the role these individuals play for their corporate employers, managers may benefit from identifying these individuals to leverage their entrepreneurial interests as well as to shield firms from potential negative consequences. For example, employees with entrepreneurial preferences may be particularly open to engaging in corporate entrepreneurship, helping firms' efforts to explore new markets and product domains. On the other hand, failure to understand and address employees' entrepreneurial interests may lead to higher turnover, limiting firms' ability to benefit from their human capital and increasing the risk that employees leave to start competing firms (Campbell et al. 2012).

Overall, attention to employees' ability as well as career preferences and to their joint role in shaping employment outcomes promises to enrich our understanding of many interesting and important issues in the areas of entrepreneurship, innovation, and human capital.

## Acknowledgments

The authors thank colleagues and conference discussants for extremely helpful comments, including, among others, Kevin Bryan, Diane Burton, Waverly Ding, Gary Dushnitsky, Dietmar Harhoff, David Hsu, Danny Kim, Aija Leiponen, Raviv Murciano-Goroff, Abhishek Nagaraj, Paige Ouimet, Yuan Shi, Evan Starr, Scott Stern, and Natalia Zinov'yeva. The authors also thank seminar participants at Boston University, Copenhagen Business School, Duke University, European School of Management and Technology Berlin, London Business School, National Bureau of Economic Research Entrepreneurship Working Group, New York University, Politecnico di Milano, Stanford University, Stockholm School of Economics, Syracuse University, Tilburg University, University of California San Diego, University of Illinois Urbana-Champaign, University of Maryland, University of Minnesota, University of Pennsylvania, University of Toronto, University of Utah, and University of Zurich for their helpful feedback. The authors greatly appreciate the constructive and insightful comments and suggestions from the anonymous associate editor and three referees. Finally, the authors thank the survey respondents who made this study possible through their continued participation for almost a decade.

## Endnotes

<sup>1</sup> VC-backed ventures have reduced much of their technological and market uncertainty, allowing them to attract higher levels of funding to support growth. As such, they possess the resources to compete in the labor market by offering higher salaries to talented employees (Kim 2018).

<sup>2</sup> Although graduates with advanced technical skills are likely to have other employment opportunities if a startup fails, survey evidence confirms that PhDs see job risk as a major disadvantage of startup employment (Roach and Sauermann 2010).

<sup>3</sup> An important body of research in labor economics studies the "positive assortative matching" of high-ability workers with other

high-ability workers or high-quality firms (Becker 1973). We draw upon this literature to guide our discussion of how high-ability workers might choose between jobs in startups or established firms (i.e., focusing on the supply side). Our discussion and empirical findings also speak to “negative assortative matching,” whereby high-ability workers match with lower quality firms (Eeckhout 2018). We thank the associate editor and two reviewers for suggesting these connections.

<sup>4</sup> Whereas data on startup employee earnings and equity are exceptionally rare, a media report using AngelList data estimated that the average early stage startup employee does not earn more than the average established firm employee when considering the low rate of successful startup exists and employee equity stakes: <https://80000hours.org/2015/10/startup-salaries-and-equity-compensation>.

<sup>5</sup> Roach and Sauermann (2015) consider entrepreneurial preferences in an absolute sense (i.e., interest in a particular career above a certain level, independent of interest in other careers). Because we examine the relationship between preferences and job choice, we use a relative conceptualization of preferences.

<sup>6</sup> Although we focus on preferences for different job attributes, career preferences may be shaped by social influences, such as departmental norms regarding entrepreneurship or founder role models (Stuart and Ding 2006, Roach and Sauermann 2015, Azoulay et al. 2017) as well as individuals’ “identity” with different occupations (Akerlof and Kranton 2000).

<sup>7</sup> Indeed, studies show that most founders transition to entrepreneurship from wage employment (Burton et al. 2002). In our survey data, among industry PhDs who aspired to become an entrepreneur during graduate school, 19% founded a startup and 81% worked in other firms after graduation.

<sup>8</sup> Consistent with prior literature, we conceptualize preferences as stable at least in the near term (i.e., between graduate school and individuals’ first job search) (Halaby 2003, Stern 2004, Elfenbein et al. 2010). Although we expect that stated career preferences significantly shape early employment outcomes, we recognize that some individuals may initially choose other types of jobs for certain short-term benefits, such as gaining industry knowledge or to discover entrepreneurial opportunities. As such, career preferences are not perfect predictors of first time job choices.

<sup>9</sup> For example, lower quality startups may be less attractive to startup types than high-quality startups and perhaps even than established firms if they offer less interesting or less cutting-edge technologies or if they seem very likely to fail. Consistent with this idea, Bryan et al. (2022) show that information about startup quality influences workers’ beliefs about a startup’s potential success and the likelihood of workers applying to that startup.

<sup>10</sup> We assume that firms hire primarily for ability and that workers’ preferences, which are typically unobservable to prospective employers, play little role in hiring decisions.

<sup>11</sup> This survey was approved by the Georgia Tech institutional review board (IRB), protocol #09152, and Cornell University IRB, #1707007286A003.

<sup>12</sup> Although our discussion highlights differences between startups and established firms, we assume that they compete with each other in the same PhD labor market. Information on overlapping job applications and offers support this assumption (Section 4.4). This labor market is quite competitive as evidenced by extremely low unemployment and earnings that are well above national population averages (National Science Board 2014).

<sup>13</sup> To examine the representativeness of our sample, we benchmarked it to the Survey of Doctorate Recipients (SDR) conducted by the U.S. National Science Foundation. Our sample is comparable to the SDR in terms of the share of recent doctorates employed in

industrial R&D as well as the share of PhDs across fields of science and engineering (details available from the authors).

<sup>14</sup> In our sample of industry PhDs, 77% went directly to industry after graduation, and 23% first did a postdoc.

<sup>15</sup> To measure firm age, we asked survey respondents whether their employer was founded within the past 5 years, 6–10 years, or greater than 10 years when they started employment. LinkedIn provides the firm founding year, which we subtracted from the first year of employment and coded to correspond to the survey measure. To measure firm size, respondents were asked to report the total number of employees using a range of categories, including 1–10 and 11–50 employees. LinkedIn also reports the number of employees using the same categories. Because LinkedIn employer size is updated regularly, we manually searched news articles and other sources for information to confirm the number of employees at the time of first employment for young firms with more than 50 employees.

<sup>16</sup> Although we interpret PhD department rank as a proxy for ability, it may also reflect other factors such as university status.

<sup>17</sup> PhD department rankings are not available for some university departments. In such cases, we used the broad field average (e.g., the average of all engineering departments when a specific engineering department ranking is missing).

<sup>18</sup> Results are substantively identical when using the raw measure.

<sup>19</sup> Among founder types, 89% also reported that a startup career was either “extremely attractive” or “attractive” compared with 63% who reported that an established firm career was either “extremely attractive” or “attractive.”

<sup>20</sup> Our approach of coding preferences as relative differs from that used by Roach and Sauermann (2015), who classify all respondents who were attracted to working in a startup and did not have founder intentions as joiners regardless of their interest in other careers such as established firms.

<sup>21</sup> In our sample of PhDs, other types are primarily attracted to university faculty careers.

<sup>22</sup> Online Table A3 shows more detailed results using the separate measures of the attractiveness of different careers.

<sup>23</sup> VC data come from PricewaterhouseCoopers MoneyTree (<https://www.pwc.com/us/en/technology/moneytree/explorer.html>) and GDP data from the Bureau of Economic Analysis ([https://www.bea.gov/iTable/index\\_nipa.cfm](https://www.bea.gov/iTable/index_nipa.cfm)). We also estimated models that included job year fixed effects instead of annual VC funding and GDP growth rate with substantively identical results.

<sup>24</sup> Analyses using linear probability models yield the same results (see Online Table C1).

<sup>25</sup> Regressions using ability quartiles show that workers in the highest quartile are more than twice as likely to work in a startup compared with workers in the lowest quartile (odds ratio of 2.09,  $p < 0.001$ ), consistent with the patterns observed in Figure 2(a).

<sup>26</sup> A one standard deviation increase in the independent variable increases the likelihood of working in a startup by 15.0% for risk tolerance, 13.8% for a preference for autonomy, and 11.6% for a preference for engaging in commercialization activities.

<sup>27</sup> Compared with established firm types, founder types are more than five times as likely (odds ratio of 5.105) and joiner types more than three times as likely (odds ratio of 3.324) to work in a startup.

<sup>28</sup> One might be concerned that lower ranked departments have a higher share of international PhDs, introducing a spurious correlation between department rank, visa requirements, and employment outcomes. Our results are robust to a model that excludes international students from the sample.

<sup>29</sup> The entrepreneurial context variables may overcontrol by capturing variation across departments that should legitimately be interpreted as reflecting individuals' ability. For example, fixed effects for Boston and San Francisco control for not only entrepreneurial context, but also for the objectively higher ability of graduates in our sample from Harvard, MIT, Stanford, and Berkeley. For this reason, we include these variables as a robustness check rather than as controls in all our models.

<sup>30</sup> Note that the coefficients of these variables should not be interpreted as traditional interactions. Our set of combination variables captures mutually exclusive groups, and the regressions do not include separate main effects of ability and preferences.

<sup>31</sup> Data on job search are only available for individuals who responded to the employment survey. We replicated our main analyses in Table 3 using this smaller sample with identical results, alleviating concerns of potential nonresponse bias.

<sup>32</sup> We thank an anonymous referee for suggesting this analysis.

<sup>33</sup> This analysis also includes responses from a 2019 survey wave.

<sup>34</sup> We note that this simple analysis focuses on the first employer type and does not account for more complicated mobility patterns, such as workers moving from startups to established firms or vice versa.

<sup>35</sup> Restricting the sample to individuals who received job offers from both startups and established firms, we find that those who chose to work in established firms are more than five times as likely to report that higher pay (odds ratio 5.49) and job security (odds ratio 5.75) were very important reasons for their job choice than those who chose to work in startups (details available from the authors). These results suggest that low pay and job security are key reasons why workers turn down startup job offers.

<sup>36</sup> We thank an anonymous reviewer for this idea.
